

Minimum Spanning Tree problem

Data structures

Fall 2018

Minimum-Cost Spanning Tree

- Given a weighted connected undirected graph:
- find a spanning tree that has minimum cost
(cost of spanning tree is sum of edge costs)

Example

- Network has 10 edges.
- Spanning tree has only $n - 1 = 7$ edges.
- Need to either select 7 edges or discard 3.

Edge Selection Greedy Strategies

- Start with an n -vertex 0 -edge forest.
Consider edges in ascending order of cost.
Select edge if it does not form a cycle together with already selected edges.
 - Kruskal's method.
- Start with a 1 -vertex tree and grow it into an n -vertex tree by repeatedly adding a vertex and an edge. When there is a choice, add a least cost edge.
 - Prim's method.

Edge Selection Greedy Strategies

- Start with an n -vertex forest. Each component/tree selects a least cost edge to connect to another component/tree. Eliminate duplicate selections and possible cycles. Repeat until only 1 component/tree is left.
 - Sollin's method.

Edge Rejection Greedy Strategies

- Start with the connected graph. Repeatedly find a cycle and eliminate the highest cost edge on this cycle. Stop when no cycles remain.
- Consider edges in descending order of cost. Eliminate an edge provided this leaves behind a connected graph.

Kruskal's Method

- Start with a forest that has no edges.
- Consider edges in ascending order of cost.
- Edge (1,2) is considered first and added to the forest.

Kruskal's Method

- Edge (7,8) is considered next and added.
- Edge (3,4) is considered next and added.
- Edge (5,6) is considered next and added.
- Edge (2,3) is considered next and added.
- Edge (1,3) is considered next and rejected because it creates a cycle.

Kruskal's Method

- Edge (2,4) is considered next and rejected because it creates a cycle.
- Edge (3,5) is considered next and added.
- Edge (3,6) is considered next and rejected.
- Edge (5,7) is considered next and added.

Kruskal's Method

- $n - 1$ edges have been selected and no cycle formed.
- So we must have a spanning tree.
- Cost is 46.
- Min-cost spanning tree is unique when all edge costs are different.

Prim's Method

- Start with any single vertex tree.
- Get a **2**-vertex tree by adding a cheapest edge.
- Get a **3**-vertex tree by adding a cheapest edge.
- Grow the tree one edge at a time until the tree has **$n - 1$** edges (and hence has all **n** vertices).

Sollin's Method

- Start with a forest that has no edges.
- Each component selects a least cost edge with which to connect to another component.
- Duplicate selections are eliminated.
- Cycles are possible when the graph has some edges that have the same cost.

Sollin's Method

- Each component that remains selects a least cost edge with which to connect to another component.
- Beware of duplicate selections and cycles.

Greedy Minimum-Cost Spanning Tree Methods

- Can prove that all the algorithms return a minimum-cost spanning tree.
- Prim's method is fastest.
 - $O(n^2)$ using an implementation similar to that of Dijkstra's shortest-path algorithm.
 - $O(e + n \log n)$ using a Fibonacci heap.
- Kruskal's uses union-find trees to run in $O(n + e \log e)$ time.
